A new facility called the Message Coordinator has been added to the initializer. It allows the initializer to run multiple terminal channels, and lets the daemons run without terminals of their own, sending their messages to the initializer for disposition.

The system also has the ability to login the daemons automatically or on operator request.

Many miscellaneous improvements have been made to the operation of the initializer and to the messages it produces.

This document has two parts: the first part describes the external changes made to the operation of the initializer, from the point of view of the operator. The second part of this document goes into more detail about the internal changes made to the initializer programs, from the point of view of the system programmer.
Changes to **Initializer** Messages

Several of the messages typed by the initializer have been shortened, to make the system bootload sequence faster.

The first message typed by the system at bootload will be a message of the form:

```
Multics SYSID - MM/DD/YY HHMM.S est DAY
```

giving the system ID and the date and time.

The system will then request one of the ring-1 commands by typing:

```
Command:
```

The legal commands are still "reload," "startup," "multics," "standard," "bos," and "shutdown," but this list will not be typed unless the operator gives an incorrect command.

When the operator types "startup," "multics," or "standard" no comment will be made during the crossing into ring 4. Instead of "Command:" in ring 4, the initializer merely types

```
R
```

to indicate that another command may be issued.

The time which prefixes initializer messages has been shortened to four digits only. The time will be followed by an abbreviation for the "source" from which the message came. For example,

```
1322 as LOGIN 2741 501 tty194 Smith.Multics
```

is the form of a login message. The "as" above identifies the message as coming from the answering service source.
System Startup

A special list of commands can be set up by the system programmers to be executed when the answering service is started. These commands are kept in "system_start_up.ec", and come in two sections: those executed before the answering service is started, and those executed just after the answering service comes up.

Normally, the system_start_up.ec will turn on the message coordinator before running the answering service, and will automatically log in the daemons immediately after the answering service is ready. If the initializer is to operate more than one terminal channel, the additional channels will be attached automatically at this time.

The normal mode of operation for the system will be to use the system master console (BOS typewriter) as the first initializer console, and to automatically add one or more terminal channels to the initializer during startup.

The startup sequence on the system console will look like this:

```
o) BCOT
s) MLTICS 19.1 - 02/14/72 1949.3 EST WED
s) Command:
o) STARTUP
s) R
```

Lines typed by the system are indicated (in this document only) by "s)" and lines typed by the operator are indicated by "o)". After the "R", the system console will not be used for most output except for the usual disk error, tape mount, programmer, and hardcore error messages.

If channel "tty192" is the terminal channel which will be used by the initializer for regular messages, it will be hard-wired to the system or the operator will have dialed it up before typing BOOT, as usual. The output on this console will look like this:

```
s) tty192 attached by system control.
s) 1950 as MLTICS 13.6; answering service 6.12
s) 1951 as LOGIN Daemon io1 io1 IO.SysDaemon
s) 1951 as LOGIN Daemon bk bk Backup.SysDaemon
s) 1952 io1 IO DAEMON READY TO START
s) --> io1
s) 1952 bk r 1952 4.801 25+99
s) --> bk
```

The lines beginning with "-->" indicate that the source waits input. They are called "sentinels." To input a line to the daemon, the operator uses the "reply" command.
Message Coordinator

```
<table>
<thead>
<tr>
<th>Message</th>
<th>Coordinator</th>
</tr>
</thead>
<tbody>
<tr>
<td>s) reply bk start_dump sys_dirs xyz</td>
<td></td>
</tr>
<tr>
<td>o) reply bk start_dump sys_dirs xyz</td>
<td></td>
</tr>
<tr>
<td>s) 1953 io1 act_ctl_: IO Daemon accounting initialization.</td>
<td></td>
</tr>
<tr>
<td>s) 1953 io1 Is this the first or seconco IO daemon?</td>
<td></td>
</tr>
<tr>
<td>s) --&gt; io1</td>
<td></td>
</tr>
<tr>
<td>s) 1953 bk Enter primary dump-tape label:</td>
<td></td>
</tr>
<tr>
<td>s) --&gt; bk</td>
<td></td>
</tr>
<tr>
<td>o) reply bk IC-75</td>
<td></td>
</tr>
<tr>
<td>o) reply io1 first</td>
<td></td>
</tr>
<tr>
<td>s) --&gt; io1</td>
<td></td>
</tr>
</tbody>
</table>
```

and so forth. The example above shows how the system intermixes output lines from all of the sources on a single console, and how the operator replies to a request for input from a source.

If more than one terminal channel is connected to the initializer, the output from the various sources (daemon processes, etc.) can be routed to divide the work between several consoles. For example, all the daemons could be handled by one terminal, and the answering service could use another. Or, if all the terminals are broken, the system can be run completely from the system console (but this setup would be bad for the system, since whenever the operator is typing in or the system is typing out on the system console, the entire Multics system is hurt; and on a two-cpu configuration, the system may crash if a ring-zero message has to wait too long for the master console.)

All terminals attached to the initializer may input initializer commands. (It is possible to restrict a terminal to only certain commands, but this will not be done at first.)

It is sometimes difficult to input an operator command between output messages on an initializer terminal, because the system keeps interrupting. If the operator types an empty line on an initializer terminal, the system will respond

```
OPER: 
```

and suspend output on that terminal channel. When the operator completes his command, the output will be restarted, with no messages lost. If the operator does not finish his command in one minute, the output will be restarted. (This feature does not work for the bootload console.)

Admin mode and editing of the message of the day can be done from any initializer terminal; but only one terminal can be operating...
Terminals may also be added to the Initializer dynamically. To do this, the operator dials a terminal into Multics as if he were going to log in, but instead of typing "login", he issues a "dial" command:

s) Load = 41.0 out of 50.0 units; users = 41
o) dial system

An optional identifier may be typed after "system," to indicate which terminal has dialed up, or to serve as a password to insure that the command has been issued by an authorized operator. The dialed terminal will then get a message of the form

s) TTY37 405 chn tty196 dialed to Initializer.

Also, or the Initializer console, a message stating that the terminal has dialed up will be printed.

s) 1137 as dial_ctl tty37 405 tty196 dialed to Initializer.

The operator should then issue a series of commands to accept the terminal channel and to route output to it:

o) accept tty196
s) R
o) define vc2 tty tty196
s) R
o) route dumb user_i/o vc2
s) R

The response on the dialed terminal will be a message saying that the Initializer has attached the channel:

s) tty196 attached by system control,

followed by whatever messages are routed to the terminal channel.

When the operator is finished with a dialed terminal, or if a curious user tries to dial the Initializer without permission, the operator may disconnect the channel from the Initializer and make it available for dialups again by typing a "drop" command:

o) drop tty196
s) R

The response on the dialed terminal will be a message like "please reissue dial command," and at this point the terminal may be re-dialed, or used for regular logins, or hung up.
Error Messages

If the operator types a command with any of the illegal characters ";" or "[" in it, the system will respond with the message

 syntax error

and ignore the command.

If a terminal is restricted to issuing only certain commands and attempts to issue a command it is not allowed, the system will respond

 privilege error

and ignore the command.

If a terminal attempts to enter admin mode, reconfigure the system, or edit the message of the day, and some other terminal is already doing either of these operations, the system will respond

 function busy,

and ignore the command.

Other error messages will be found in MOSN-XXX, "Initializer Messages".

Difficulties

Occasionally, the message coordinator may stop operating due to an ITT overflow, a device read error, or other system problem. Try issuing the "reset" command in such a case. This will attempt to restart all channels. Channel restart is also attempted if system control encounters any fault.
Daemon Operation

The daemon processes have not been changed in any way by the installation of the message coordinator. They type the same messages, and expect the same input; their input and output is, however, passed through the initializer or its way to and from the terminal channel.

To cause a daemon to be logged in from the initializer, the operator may type

```
login Personid Projectid sourceid
```

The daemon will then log in, and attach its input and output to the initializer, as a source with name "sourceid." For example, a second IO daemon can be logged in by typing

```
o) login IO SysDaemon io2
s) R
s) 1721 as LCGIN Daemon io2 io2 IO.SysDaemon
```

or a complete dump may be started by typing

```
o) login Dumper SysDaemon dump
s) R
s) 1721 as LCGIN Daemon dump dump Dumper.SysDaemon
```

To cause a daemon to log out, the operator issues the "logout" command from the initializer, giving the person and project id of the daemon. Thus, to log out the daemon, the operator types

```
o) logout Dumper SysDaemon dump
s) R
s) 2231 as LOGOUT Daemon dump dump Dumper.SysDaemon 12:11
```

To cause all daemon processes to be logged out, when the system is being shut down, the operator types

```
logout ***
```

Occasionally, the operator needs to send a "quit" to a daemon process. A special command is required because the ALT or INTERRUPT button on an initializer terminal is connected to the initializer, not to the daemon, and will be ignored by system control. To send a quit to a daemon, the operator must type

```
quit sourceid
```

and the daemon will accept the quit after it has been passed from the initializer.
Interface Improvements and Bugs Fixed

The fault message typed on an error in the initializer is no longer missing the first character of every line.

Faults during a reload are no longer fatal.

The information typed when a fault occurred in the initializer process used to be slightly garbled; this bug has been fixed, and furthermore once the answering service is running the fault information will be written into a cuno file rather than typed on the console.

QUIT is now allowed in the initializer until the answering service or the message coordinator has been started.

On the development machine, if the admin mode password is "*", the password will not be requested and admin mode will be entered immediately.

The "entering admin mode" message has been removed. The ready message from the listener is sufficient confirmation that admin mode has been entered.
The rest of this document is intended for system programmers who need to know how the message coordinator operates, and what the system commands are which affect the use of initializer terminal channels.

Overview

There are three major components to the message coordinator implementation: a major revision of system_control to handle multiple input consoles, a new program called the message coordinator which handles multiple output consoles and message routing, and a new device interface module called the "message routing DIM" ("mrd"), which does input and output to special data segments instead of on a terminal channel.

The message coordinator relies heavily on the interprocess communication event-call facility. The following kinds of event call channels are used in the initializer process:

<table>
<thead>
<tr>
<th>Event</th>
<th>Procedure Calls</th>
</tr>
</thead>
<tbody>
<tr>
<td>tty read completion</td>
<td>system_control_$tty_aught</td>
</tr>
<tr>
<td></td>
<td>dialup_</td>
</tr>
<tr>
<td></td>
<td>message_coordr_$router</td>
</tr>
<tr>
<td>message from daemon</td>
<td>message_coordr_$typer_out</td>
</tr>
<tr>
<td>output queued for tty</td>
<td>message_coordr_$typer_out</td>
</tr>
<tr>
<td>alarm wakeup</td>
<td>dialup_</td>
</tr>
<tr>
<td></td>
<td>system_control_$tty_aught</td>
</tr>
<tr>
<td></td>
<td>act_ctl_</td>

</tr>
<tr>
<td>user process signal</td>
<td>dialup_</td>
</tr>
<tr>
<td></td>
<td>dial_ctl_</td>
</tr>
<tr>
<td></td>
<td>absentee</td>
</tr>
<tr>
<td>administrator command</td>
<td>system_control_$admin_co_nlr</td>
</tr>
</tbody>
</table>

The first console attached by system_control_ is handled differently from the rest of the initializer terminal channels. Output to it is written on the stream "master_i/o", and input from it is read directly through ios_. The initializer process's single block point is in the DIM which handles this first console. Additional terminal channels are handled by event-call
Message Coordinator

Internal charges

Procedures (tty_aught for input, typer_out for output) which perform I/O directly on the channel without the use of ios_.

The main data bases which are used by the message coordinator are:

- mc_anstbl: one entry per device channel
- MRT: message routing table
- vcons_tab: virtual console table
- mc_message: incoming messages for initializer
- xxx_message: input messages for other sources
- ttyxxx_queue: queued output messages for devices

These tables are all completely reconstructed every time the message coordinator is started. All of these segments are kept in /system_control_dir. Their ring brackets should be 4,4,4, and access should be RW for the initializer and for the daemon processes, and null for everybody else.

There are several commands which system programmers may use to find out the status of the message coordinator tables.

- dump_mrt: dump Message Routing Table
- dump_vct: dump Virtual Console Table
- dump_devq: dump device queue
- dump_msg: dump source message segment
- restart_chn: attempt to restart device queue

Consult the writeups of these commands in the SPS for details of their use.
System startup deck implementation

The segment "system_start_up.ec" located in the directory 
>system_control_dir is used to cause the whole message 
coordinator facility to be invoked automatically when the system 
is started up. This exec_com is invoked twice, once before the 
answering service is initialized and once after. Its first 
argument is "part1" on the first call and "part2" on the second 
call.

The following is an example of a system_start_up.ec:

& MIT system startup deck
&
&command_line off
&goto &1
&
&label part1
system_control_$command mc
admin$accept tty192
admin$redefine default_vcons otw tty tty192

system_control_$command reply lo1 start
&quit
&
& end
The example given defines a number of items:

**DESTINATIONS**

- *otw*  Operator's console (POS console)
- tty192  Hard-wired terminal channel
- log    Log file (copy of all IO output)

**VIRTUAL CONSOLES**

* Emergency virtual console
  - default_vcons  Default virtual console
  - scc  System control console
  - asc  Answering service console
  - ioc  IO Daemon console
  - okc  Backup console
  - tpc  Tape message console

**SOURCES**

- as  Answering service (Initializer process)
- sc  System control (Initializer process)
- tape  Tape request handler (Initializer process)
- io1  First IO Daemon
- io2  Second IO Daemon
- ok  Backup Daemon
- cd1  Complete Dump (Dumper, SysDaemon)
- cd2  Complete Dump (second Dumper)
**Operator Commands for Message Coordinator**

Many new commands have been added to the initializer to support the message coordinator. They divide into six classes:

1. Commands dealing with device channels: accept, substty, and drop.

2. Commands dealing with virtual consoles: defire, redefine, and undefine.

3. Commands dealing with routing: route, reroute, and deroute.

5. Commands dealing with daemons: login and logout.

All of these commands except "reply" and "mc" are supported in the answering service program "admin." "admin" obtains and checks arguments, and calls either "message_coordr_" (for 1-4 above) or "daemon_user_manager_" (for 5).

An entry point has been added to system_control_ so that the various exec_com's and administrative commands may execute system control operator commands. Calling

```
system_control_$command reply x hello
```

will cause the system control command "reply x hello" to be executed.
Message coordinator

Command: accept
Usage: accept a device channel and connect it to initializer
Format: accept TTYXXX -RESTRICT-

This command is used to pick up a terminal channel and add it to the initializer's device complement. If RESTRICT is not specified, or if it is "full", the device will be able to issue all operator commands. RESTRICT may also be

- none no commands allowed
- reply only "reply" is allowed
- query only "who" and "hmu" are allowed

If the channel appears in the answer_table, then it must either have state 0 (not in lines file) or be dialed to the initializer.

Response: TTYXXX attached by system control.

Command: substty
Usage: swap one device for another
Format: substty TTYXXX TTYZZZ

This command causes TTYZZZ to be attached and TTYXXX to be dropped. All output queued for TTYXXX will be placed in the queue for TTYZZZ.

Response: TTYZZZ attached by system control.

Same message as for "drop" on TTYXXX

Command: drop
Usage: remove a device channel from system control
Format: drop TTYXXX

This command causes a device channel to be removed from the message coordinator. Any pending output for the channel is lost. If the channel was dialed to the initializer, it is disconnected.

Response: please reissue dial command
(only if channel was dialed)
Command: define

Usage: associate virtual console with channel

Format: define VCONS TYPE DEST

This command creates a new virtual console if VCONS does not already exist. The destination DEST is then added to the destination list for VCONS. A virtual console may have up to 8 destinations. If TYPE is "tty" then DEST must be a channel ID which has been accepted previously. If TYPE is "log" then DEST is the name of a log file to which messages will be added as they are sent to VCONS. (These logs can be printed with "print_log".) If TYPE is "sink" then DEST can be any name: output sent to a sink vanishes.

Command: redefine

Usage: interchange one destination with another

Format: redefine VCONS OLD_DEST NEW_TYPE NEW_DEST

This command removes one destination from a virtual console and adds another. NEW_TYPE and NEW_DEST are as above. If OLD_DEST is a device channel which currently has output queued for it, no more output will be queued but all the queued output will be printed.

Command: undefine

Usage: remove destination from virtual console

Format: undefine VCONS OLD_DEST

This command removes a destination from a virtual console. If VCONS is left with no destinations and output is routed to it, the output will be typed on the bootload console.
Operator commands

**Command:** route

**Usage:** direct output from a source to virtual consoles

**Format:** route SOURCE STREAM VCONS

This command sends the output from the source SOURCE writer on the stream STREAM to the virtual console VCONS. If no entry for SOURCE, or for STREAM under SOURCE, exists in the MRT, one will be created. There may be up to 16 sources. Each source may have up to 8 streams, and each stream may have up to 8 virtual consoles. VCONS must have been previously defined. It is added to the virtual console list for STREAM.

**Command:** reroute

**Usage:** change virtual console for a stream

**Format:** reroute SOURCE STREAM OLD_VCONS NEW_VCONS

This command alters the MRT entry for SOURCE and STREAM to change a virtual console entry.

**Command:** deroute

**Usage:** remove virtual console from stream

**Format:** deroute SOURCE STREAM OLD_VCONS

This command removes a virtual console from the output list for a given SOURCE and STREAM. If the stream is left with no virtual consoles, output will be sent to the default virtual console, which is usually defined to the system master console.
Message coordinator

Command: reply, r
Usage: send input line to a source
Format: reply SOURCE REST OF LINE

This command sends an input line to the given source. The input line is placed in the segment "SOURCE_message" and a wakeup sent to the source. When the source calls to read via mrd_, it will extract the message from the segment.

Command: quit
Usage: send quit to a source process
Format: quit SOURCE

This command sets a flag in the segment "mc_message" indicating that a quit has been sent. If the source process has called

ics_|$order (STREAM, "quit_enable", null, status);

on one or more of its streams attached through mrd_, the message routing DIM will check every ten seconds for the quit flag, and signal suit if the flag is on.
Command: login
Usage: operator login of daemon
Format: login PERSON PROJECT SOURCE
This command causes the login of a daemon process at operator request. The PERSON PROJECT must be a registered user with the "daemon" attribute. The outer module for the process being created is forced to be "mrd_".

Command: logout
Usage: operator logout of daemon
Format: logout PERSON PROJECT SOURCE
This command causes the logout of a daemon process at operator request. If PERSON, PROJECT, or SOURCE is "*", all users which match are logged out. SOURCE, or SOURCE and PROJECT, may be omitted, and are then assumed to be "*".
Message coordinator

Command: mc
Usage: start message coordinator
Format: mc

This command causes system control to start the message coordinator.
Message Coordinator

Several additional improvements to the message coordinator and initializer have been deferred for the present.

1. System control should be modified so that the special characters "[" and ":" can be sent to a daemon.

2. Some way of handling arguments to "startup" so that the operator can skip or modify parts of system_start_up.ec should be invented.

3. For installations which have initializer terminals in multiple locations, some indication that a command has been typed at another terminal should be provided. Currently, it is possible for a terminal to issue a command which causes output on some other terminal, and the output terminal has no indication of what caused the output.

4. Along with the above facility, installations with multiple, separated initializer terminals may wish to have an "intercom" feature. Such a facility can be provided now, in an inconvenient fashion.

5. An initializer command which lists the current device complement and routing should be provided. This command should produce output in the form of "route", "define", and so on so that its output can be used to take a temporary change to the standard routing, resulting from initializer message coordinator commands after startup, and make it permanent in system_start_up.ec.

6. A facility for the automatic dprinting of log files, either at a given time interval or whenever the log becomes full, should be worked out.
